

### **chemical beam epitaxy and pdf**

In molecular beam epitaxy (MBE), a source material is heated to produce an evaporated beam of particles. These particles travel through a very high vacuum ( $10^{-8}$  Pa; practically free space) to the substrate, where they condense. MBE has lower throughput than other forms of epitaxy.

### **Epitaxy - Wikipedia**

Metalorganic vapour phase epitaxy (MOVPE), also known as organometallic vapour phase epitaxy (OMVPE) or metalorganic chemical vapour deposition (MOCVD), is a chemical vapour deposition method used to produce single or polycrystalline thin films. It is a highly complex process for growing crystalline layers to create complex semiconductor multilayer structures.

The possibility to produce Ni-base superalloy single crystals by selective electron beam melting (S-EBM) is demonstrated. The production of single crystals specimens was achieved by a tight control of the processing conditions without requiring a grain selector or a crystal seed.

Gate-induced massive and reversible phase transition is demonstrated in VO<sub>2</sub> channels using solid-state proton electrolytes. Applying gate bias effectively injects large numbers of H<sup>+</sup> ions without creating oxygen deficiencies and causes a two-step insulator-to-metal-to-insulator phase transition and a hydrogen-defect-induced chemical expansion at room temperature.
